Rigid electromagnetic actuators have a variety of applications, but their bulky nature limits human-actuator integration or machine-human collaborations. In a new report on *Science Advances*, Guoyong Mao and a team of scientists in soft matter physics and soft materials at the Johannes Kepler University Linz, Austria, introduced soft electromagnetic actuators (SEMAs) to replace solid metal coils with liquid-metal channels embedded in elastomeric shells. The scientists demonstrated the user-friendly, simple and stretchable construct with fast and durable programmability.

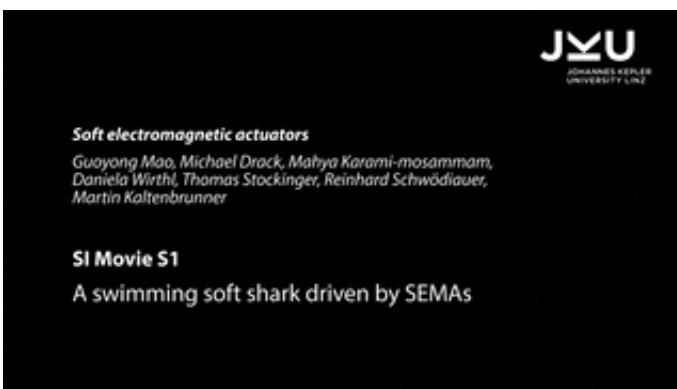

They engineered a SEMA based soft miniature shark and a multi-coil flower with individually controlled petals, as well as a cubic SEMA to perform arbitrary motion sequences. The team adapted a [numerical model](#) to support device miniaturization and reduce [power consumption](#) with increased mechanical efficiency. The SEMAs are electrically controlled [shape-memory](#) systems with applications to empower soft grippers for minimally invasive medical applications. The scientists highlighted the practicality of small size and multi-coil SEMAs for promising applications in medicine, much like in the classic sci-fi movie "[Fantastic Voyage](#)," in which a miniature submarine destroyed a blood clot to save a patient's life. In reality, Mao et al. aim to develop and deploy SEMA-based advanced microrobots for such futuristic medical applications, including drug delivery and tissue diagnostics with nano-precision.

## Robots and their applications

Robots are actively introduced into a variety of technical fields ranging from industrial production to autonomous transport, public security, and

as personal assistants in medicine—in close contact with humans. The use of [robots to perform surgery](#) via guided [magnetic resonance](#) imaging (MRI) is gaining attention, and future applications will seek to advance safe robot-human interactions.

Since [Michael Faraday's demonstrations](#) of the rudimentary electric motor in 1821, electromagnetic motors that form the core of conventional robots have undergone numerous changes. The interplay of rigid materials such as copper or iron used for such devices can be harmful for collaborations with the human body, imposing a major drawback to the development of new and soft functional actuators that are sensitive to [a variety of triggers](#), including heat, humidity, pH, light and electric or magnetic fields. Furthermore, soft, functional actuators are limited by slow response times and difficulty in [precise control](#) during real-life applications. It is therefore more practical to reform the structure and materials to engineer [soft electromagnetic actuators](#) (SEMA). (SEMA).

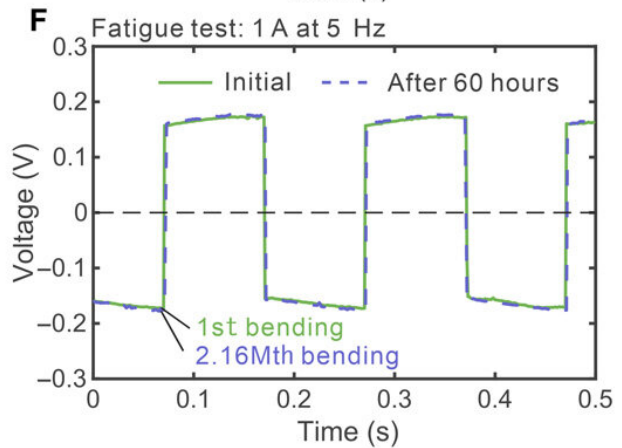

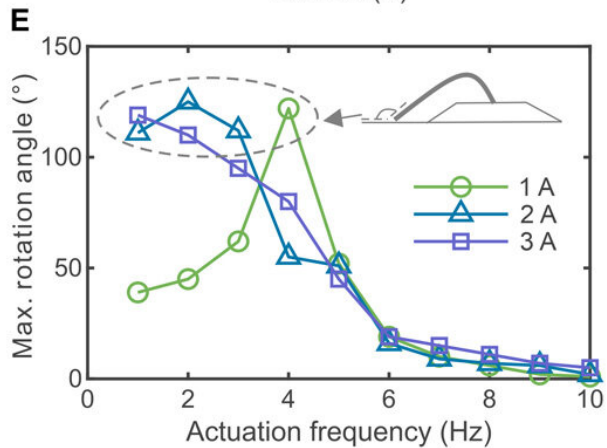

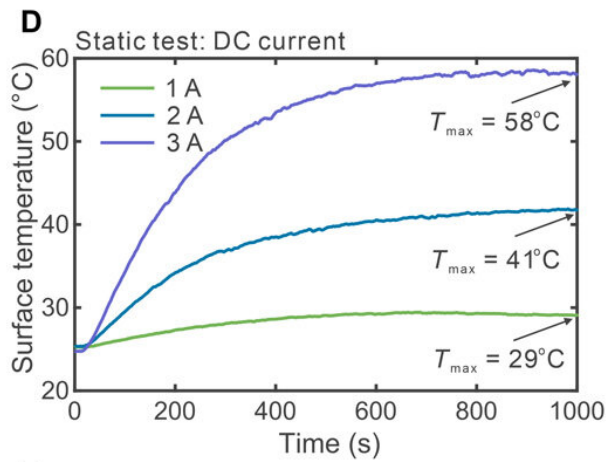

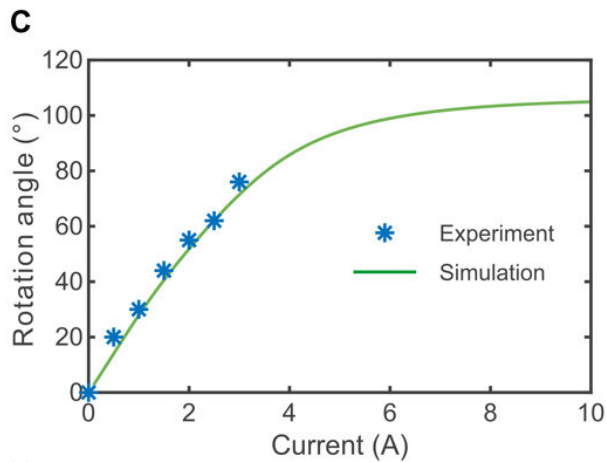

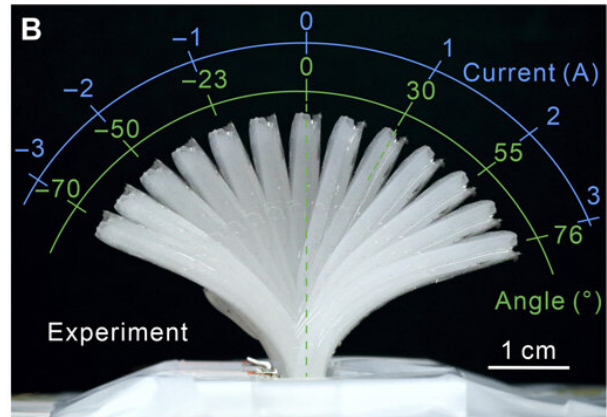

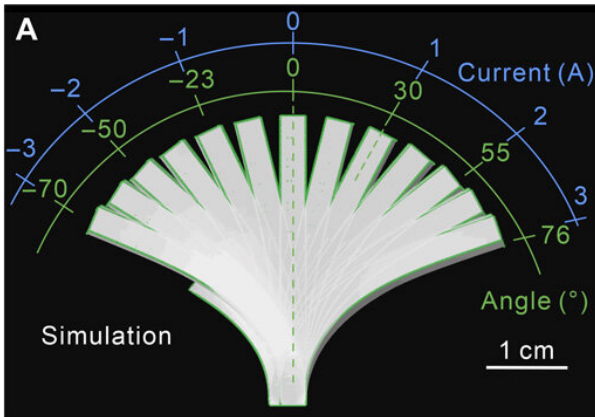

A swimming soft shark driven by SEMAs. SEMAs act as tail and fins. The driving current is a square wave with 3 A @ 4 Hz. The fish is put at the center of the magnet with the axis of the fish along the asymmetric axis of the plate magnet. Turning the current on and off drives the shark through the water. ## Designing and developing high-performance soft electromagnetic actuators (SEMAs)

In this work, Mao et al. presented several methods to design and develop high performance soft electromagnetic actuators to power soft forms of robotics. They explored six main design strategies, where the new class of SEMAs replaced hard, rigid structures of conventional direct current (DC) motors with liquid-metal channels embedded in a soft elastomer shell. In its working principle, when a current is sourced through the conductive channel, a single-coil square SEMA will bend, allowing it to act as a motor for soft robotics. They used a driving voltage below 1 V, which was harmless, and even allowed underwater functions; the scientists demonstrated the concept with a swimming shark made of SEMA-based fins and a tail. Mao et al. modeled the SEMAs as a series of conductive wires in a magnetic field and calculated the driving force according to the [Lorentz force law](#), and examined the distribution of the magnetic field to design and actuate SEMAs.

In this work, the team used a plate magnet and characterized the quantitative magnetic field via experiments and simulations. The results showed the need for low electrical resistance to operate the SEMA, which Mao et al. achieved by using liquid metals as the stretchable conductor in the construct. They incorporated molding as a [frugal approach](#) to achieve precisely patterned elastomers and well-sealed liquid-metal channels.

Characterization of a single-coil square SEMA. Rotation angle of the SEMA subjected to a DC current from 1 to 3 A (A) predicted in the simulation and (B) observed experimentally. (C) Rotation angle of the SEMA as a function of the current for experiment and simulation. (D) Temporal change of the surface temperature of the SEMA for three specific values of DC current, 1, 2, and 3 A. (E) Maximum rotation angle of the bending SEMA subjected to square wave

currents, with varying amplitude and frequency. Inset: Maximum rotation angle is limited by the actuator touching the ground. (F) Fatigue test with 5 Hz at a current of 1 A. Comparison of the voltage drop versus time at the beginning and the end of the test shows a perfect overlap of the first and the 2.16 Mth bending cycle, evidencing the high durability of the SEMA. Credit: Science Advances, doi: 10.1126/sciadv.abc0251

## Optimizing SEMAs for improved performance and proof-of-concept applications

By increasing the magnetic field in the experiment, the scientists increased the strain energy of actuation of the construct. They could also increase the strain energy of SEMAs by increasing the amplitude of the current, although joule heating effects could increase heat and temperature in the set up. The team achieved a decreased resistance of the SEMA by adding [conductive particles like copper](#) for improved performance of the device. Mao et al. then conducted a series of actuation frequency tests to investigate the performance of SEMAs. They used prolonged fatigue tests (actuation at 5 Hz frequency for 60 hours) and showed how a single-coil square SEMA could be bent 2.16 million times without any changes in performance. The scientists then miniaturized SEMAs via a [diverse array of techniques](#).

Function of a fish-tail SEMA. A fish-tail like SEMA is placed at the bottom of a water tank to demonstrate the safe operation in water without additional isolation due to the low driving voltage. A magnetic field applied by a plate magnet placed underneath the tank, lets the SEMA swing like a fish-tail when applying a 3 A square wave current. The solid blue dye dripped into water at the beginning of the experiment is rapidly mixed depicting the high performance of the SEMA. Credit: Science Advances, doi: 10.1126/sciadv.abc0251.

To further determine the power of SEMAs, the team built a double-coil square to provide a higher force beyond a single-coil version. The maximum output power of SEMA was about 57 mW, while the maximum power density reached 5.3 mW/g. With time, the efficiency decreased as the current increased, while most of the power dissipated as heat to the environment. After optimization, the team noted the remarkable flexibility of SEMAs, compared to other types of soft functional actuators. As proof-of-concept, they developed several constructs including a fish-tail SEMA in the form of a blender and a flower SEMA with five petals. The multi-coil flower SEMA demonstrated high programmability with each petal acting as a single petal to function in arbitrary magnetic fields.

**SI Movie S8**

A programmable flower SEMA

The multi-coil flower SEMA consists of five single pedals that can be controlled individually. Dynamic simulation of a single petal subjected to a current switching from 0 to 5 A shows the deformation of one single petal .

Furthermore, the single petals are actuated sequentially as well as all of them simultaneously. The petals are actuated one by one with a time interval of 10 ms, 50 ms, 100 ms and 1 s showing the outstanding dynamic performance of our SEMAs. Credit: Science Advances, doi: 10.1126/sciadv.abc0251.

In this way, Guoyong Mao and colleagues introduced a series of SEMAs for highly controlled fast actuation, where their soft-body and low driving voltage did not interfere when in contact with living organisms and fragile objects. The experiments and theoretical analyses predicted SEMAs to maintain high energy density, power density and efficiency, when subject to a strong [magnetic field](#). The SEMAs were efficiently controlled and easily programmed, allowing individual actuation of soft robotic elements in complex actuators as demonstrated with a flower SEMA. Further numerical and experimental analyses allowed the team to improve the power output and mechanical efficiency of the constructs. The new work will have extended applications in precision drug delivery, tissue diagnosis and cell manipulation.
