In recent years, many research teams worldwide have been developing computational techniques inspired by the human brain, such as deep learning algorithms. While some of these techniques are considered highly promising for a wide range of applications, conventional hardware does not always support their computational load and thus can limit their performance.

A possible solution for overcoming the limitations of existing hardware

and ensuring that brain-inspired [computational techniques](#) achieve optimal results entails the creation of new electronic components that better reflect the structure of the [human brain](#). A class of neuro-inspired computing chips is specifically designed for artificial intelligence (AI) applications that mimic the neural structures in the brain of humans and other animals.

Researchers at Tsinghua University in China have reviewed recent advancements in the design of neuro-inspired computing chips to gain insight on the progress made so far and identify challenges that still need to be overcome. Their review paper, published in *Nature Electronics*, also outlines a series of co-[design principles](#) that could inform the development of new neuro-inspired circuits, devices and algorithms.

"The idea for our paper came from our previous attempts at designing neuro-inspired computing chips," Huaqiang Wu, one of the researchers who carried out the study, told TechXplore. "In our past studies, we found that it is difficult to optimize the performance of these chips on an individual level, such as the device or circuit level, and that such a chip needs to be optimized with co-design strategies that cover a broad range of elements, from devices to algorithms."

In their new paper, Wu and his colleagues closely examine recent developments in the design of neuro-inspired computing chips and reflect on some of the lessons learned from their own efforts in the field. In addition, they outline a set of benchmarking metrics and co-design principles that could assist others who are trying to develop these chips.

"We hope that our work will help non-expert readers to find out more about neuro-inspired computing chips, while also promoting greater development in this field of research," Wu said. "We mainly examined neuro-inspired computing chips in terms of their potential for supporting algorithms, spiking neural networks or artificial (deep) neural networks."

Wu and his colleagues highlight four metrics that engineers could focus on when trying to evaluate the effectiveness of neuro-inspired computing chips: computing density, energy efficiency, computing accuracy and on-chip learning capability.

When reviewing past studies, the researchers observed that these metrics were the most crucial for the design and optimization of neuro-inspired computing chips, as they best represented the chips' unique features and their possible advantages over traditional chips. For instance, computing density, a metric that reflects a chip's area efficiency, ultimately allows engineers to determine how much information their chips can store at once and whether their memory is sufficient to run large-scale neural networks.

In addition to outlining important metrics for evaluating brain-inspired chips, Wu and his colleagues introduced a set of co-design principles that could serve as a reference for future research in the field. These principles are largely based on their past research findings and observations.

"We think that the co-design tool we proposed is the most important part of our study," Wu said. "In the practical neuro-inspired computing chip design, without this co-design tool, it is hard to achieve a high-performance chip. For example, nonvolatile memory (NVM) devices, which could be used as synaptic memory, usually have intrinsic non-idealities and these non-idealities will drop the performance of chip. Reducing the non-idealities at the device level, however, requires lots of effort, and we cannot remove them entirely. Our co-design tool could thus help to optimize the performance of a chip not only at the device level but also at the circuit or system levels."

Their review paper could ultimately serve as a general roadmap for engineers who are trying to develop brain-inspired chips. Meanwhile,

Wu and his colleagues are planning to devise other guidelines that could speed up and facilitate research in the fields of artificial intelligence (AI) and neuro-inspired electronics.

"In our future research, we could divide designing neuro-inspired computing chips into two parts," Wu said. "In the [device](#) fabrication and technology integration part, we will optimize the performance of devices, fabricate new neuro-inspired devices and explore three-dimensional neuro-inspired computing chips. In the chip and system part, on the other hand, we will develop a co-design tool and design a general-purpose neuro-inspired computing chip, especially the NVM based computing-in-memory [chip](#)."
