Recently, researchers from the Institute of Intelligent Machines

developed a new wavelength selection algorithm based on combined moving window (CMW) and variable dimension particle swarm optimization (VDPSO) algorithm.

CMW retained the advantages of the moving window algorithm, and different windows could overlap each other to realize automatic optimization of spectral interval width and number. VDPSO algorithms improved the traditional particle swarm optimization (PSO) algorithm.

This new algorithm, which is called VDPSO-CMW, could search the data space in different dimensions, and reduce the risk of limited local extrema and over fitting.

Combined with the moving [window](#) strategy, the spectral data variables could be quickly selected.

Comparing with four high-performance variable selection algorithms such as BOSS, VCPA, iVISSA and IRF, the results showed that the algorithm could select the more important spectral information and improve the predictive ability of the model.

The [algorithm](#) was expected to be further applied to [data analysis](#) in the fields of genomics, proteomics, metabolomics and quantitative structure-activity relationship.
