

Green energy transition: Early and steady wins the race

December 4 2020

What's the cheapest, easiest way to honor the Paris Agreement of limiting the global warming to 1.5 degrees Celsius? A clear and strong investment in wind and solar power. Starting now.

That's the message in a new scientific paper published in *Nature Communications*, in which Aarhus University researchers have modeled the decarbonisation of the sector-coupled European energy system using uninterrupted, high-res hourly data for every European and Scandinavian country and network interconnectivity.

Using the university's supercomputer, PRIME, the researchers have modeled how to modify the production of electricity, heating and transport sector energy to make sure that there's enough energy for every possible hour, even in the coldest weeks of winter.

"We ask the question of which energy strategy to employ in order to reach the 2050 goal. We have a carbon budget—a maximum amount of CO₂ we can emit—and how do we make sure that by 2050 we reach climate neutrality in the cheapest and most feasible way?" asks Assistant Professor Marta Victoria, an expert in photovoltaics (PV) and energy systems at the Department of Engineering, Aarhus University.

She continues: "There are two scenarios: Early and steady or late and rapid. Our model clearly shows that the cost-optimized solution is to act now. To be ambitious in the short term. And we find solar energy and onshore and [offshore wind](#) to be the cost-optimized cornerstone in a fully decarbonised 2050 energy system."

Marta Victoria says that both paths require a massive deployment of wind and solar PV during the next 30 years. The required installation rates are similar to historical maxima, making the transition challenging, yet possible.

"It's not an easy task," she says. "In some years, we will have to install more than 100 Gigawatts of solar PV and wind power, and to achieve full decarbonisation, the CO₂ prices will have to be a lot higher than today."

The paper illustrates a slowly inclining CO₂ price that maximizes around 400 €/ton in the year 2050—around 20 times higher than today's prices. This is required in order to favor the renewable transition, Marta says.

The model also includes hydro power, and to account for so-called "nightmare weeks," a small amount of gas-based electricity and heating production plus [energy](#) storage facilities: "District heating systems are efficient for very cold and critical periods when [electricity demand](#) and heating demand is high, but [wind](#) and [solar energy](#) production is low. Large hot-water tanks discharge during those weeks. This way, we make sure that the future [energy systems](#) works for every possible scenario."
