A team led by Prof. Hu Linhua at the Hefei Institutes of Physical Science of the Chinese Academy of Sciences (CAS) has recently developed a type of self-healing perovskite solar cell by functional combination of polyvinylpyrrolidone (PVP). Related results were published in the *Journal of Energy Chemistry*.

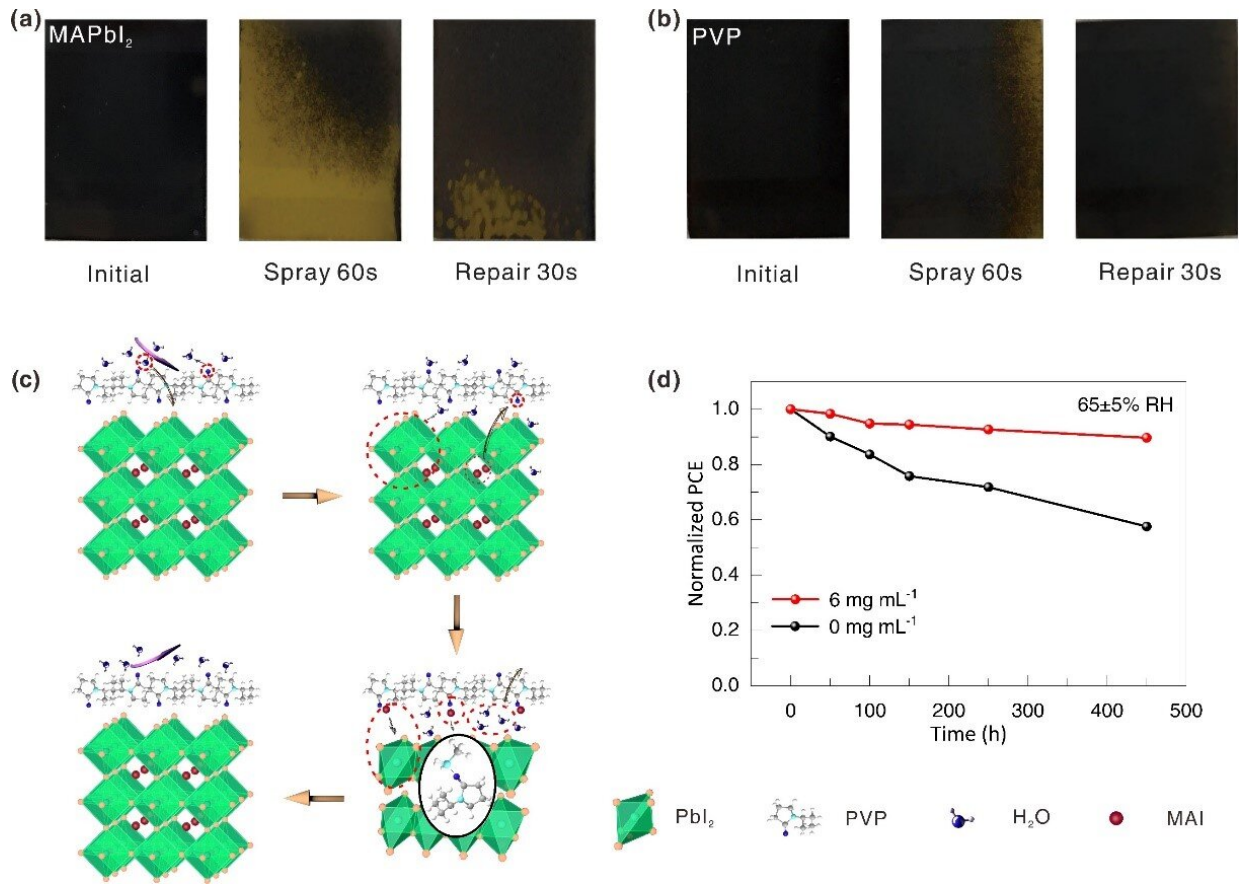

These [solar cells](#) have shown amazing humidity stability and self-healing behavior after 500 hours of operation, according to the researchers.

Organic-inorganic hybrid perovskite solar cells are considered to be a competitive alternative to conventional silicon solar cells. However, they are prone to degrading when exposed to air. Scientists have been working to make them stable and better self-healing to resist harsh operating environments.

Air moisture is the key issue for perovskites. It invades the films and accelerates the damage of devices. Therefore, the researchers introduced PVP to the methylammonium lead iodide perovskite precursor. It can control [crystal growth](#) and endow the devices with self-healing ability in a moisture environment.

PVP is a polymer with many carbonyl groups. When it was introduced in [perovskite](#) solar cells, it acted as a "protective armor with an automatic blood backflow effect" against water vapor.

In addition, PVP can improve crystal growth with fewer defects and larger grains.
