

Closed-loop technology improves energy recovery from sludge and reduces sludge disposal costs

September 1 2022

Treating wastewater in Australia produces three million tons of sludge

which then must be treated and disposed of. The process is responsible for 50% of the total operating costs of wastewater treatment plants.

A researcher from the University of Technology Sydney has developed a new treatment technology that would not only reduce the amount of waste by a third but also recover energy from the sludge itself.

The end product would also be safer biosolids for fertilizer than currently being produced.

This technology only relying on a waste by-product of wastewater treatment itself, was invented by Huan Liu, who is completing his Ph.D. at the university. Her research work has been published in *Nature* and commended by the Australian Water Industry.

"It is a closed-loop technology—the only chemical needed is a waste by-product of wastewater treatment," Huan says.

"Instead of being a contaminant for [wastewater treatment plants](#), the waste by-product becomes a useful part of the process," she says.

The process is also much more efficient at removing [pathogens](#) from the end product. Huan showed an 82% reduction in pathogens and a 20~70% reduction in antibiotic resistant genes from traditional procedures. The residue waste could achieve the Grade A biosolids according to the New South Wales Environmental Protection Agency, reducing the [health risks](#) of using the sludge as fertilizer.

Huan estimates that if the technology were applied to wastewater treatment plants in NSW alone, it would save taxpayers an estimated \$5 million a year.

The technique works in all [wastewater](#) treatment plants with [anaerobic](#)

[digestion](#) and only requires the installation of a small and simple mixing tank. The technology is being commercialized.

The estimated payback time would be less than one year, while the benefits for plants and society will be lasting.
