A multidisciplinary team made up of experts from the University of Huelva, the Miguel Hernández University and the Spanish Institute of Oceanography (IEO) has designed an innovative integrated system for monitoring fishing activity based on the use of sensors usually installed in a smartphone to detect in real time, and according to the movement of the vessel, what type of fishing activity is being carried out on board. This information is relevant in the fishing sector for estimating the amount of fish in a specific area of the sea and calculating catches.

The novelty of this low-cost app is its easy installation in any mobile device and the fast transmission of data in real time, in under a second. In addition, as reported in the study entitled "Is the vessel fishing? Discrimination of fishing activity with low-cost intelligent mobile devices through traditional and heuristic approaches," published in the journal *Expert Systems with Applications*, this tool makes it possible to determine with great precision where the vessel is located, regardless of its size, and how much time it spends fishing.

This [mobile app](#), called FAMIS, provides instant information on the working phase of a vessel. In this respect, the time a vessel spends fishing is a determining factor for assessing fishing effort, that is, for calculating the amount of catches in a particular area and the amount of fish that may be present in that place at that precise time.

Current systems for monitoring [fishing vessels](#) indicate the location of boats over a longer time interval (approximately at least every three minutes), require prior installation on the deck of the vessel, and are

controlled by the relevant fishing authorities.

These are tracking systems similar to GPS that send a signal to land. "This tool allows us to know the position of a boat, but during its stay at sea we don't know how much time it has spent casting the nets, fishing and collecting all the material. The FAMIS app goes further and makes it possible to identify from the movement of the vessel what fishing maneuver it is carrying out at all times," Fundación Descubre was told by Juan Carlos Gutiérrez Estrada, researcher at the University of Huelva and one of the authors of this study.

The experts, specialized in Computer Science, Biology and Marine Science, have applied this system because both smartphones and tablets carry integrated sensors that allow to identify the movement of the ship from the data they record. "Depending on the type of maneuver (whether the boat is accelerating, pitching, rolling, etc.), the vessel has a characteristic movement that is reflected in the accelerometer. They also allow us to know whether the vessel is casting its net, fishing or retrieving its gear," says Gutiérrez Estrada.

Artificial intelligence on board

This system, which sends information as soon as the [mobile phone](#) is placed on the deck of the boat, has been tested using different statistical methods and [artificial intelligence](#) models based on artificial neural networks and support-vector machines. The app displays numerically and graphically on its screen all the information captured by the different sensors: GPS, accelerometer, gyroscope and magnetic field. The most efficient model will be integrated into the app and will provide information about the activity that the boat is performing in real time.

To demonstrate the usefulness of these sensors, tests were carried out from the oceanographic vessel Miguel Oliver on one of its voyages. This

70-meter long and 12-meter wide vessel is equipped with technological equipment for navigation and for fishing and oceanographic research. "This [boat](#) makes it possible to record four to six net hauls per day, and to obtain data under very adverse conditions, given its large displacement and the lightweight characteristics of the fishing gear used for sampling," says the co-author of this study.

According to the experts, the model can be used with any type of vessel, as it can be calibrated and adapted for use on small boats. "The main advantage of this app for the fishing industry is its ability to count the fishing effort, a fundamental parameter for estimating the relative abundance of fish in the sea," says Gutiérrez Estrada.
