

Small communities could be buying, selling and saving money on electric power right now. Here's how

September 23 2022, by Soheil Mohseni and Alan Brent

Globally, the electricity sector is shifting from large, centralized [grids powered by fossil fuels](#) to smaller and smarter [renewable local networks](#).

One area of strong interest is "[energy arbitrage](#)," which allows users to buy and store electricity when it is cheaper and sell or use it when the cost is high.

But Aotearoa New Zealand is [slow to take this up](#)—even though it is a crucial part of the [transition to a zero-carbon future](#). Why is this?

Small-grid technologies and infrastructure are still in the experimental phase, being tested for effectiveness and desirability of [different set-ups, ownership models and commercial arrangements](#). And [intelligent energy-management systems](#) that can provide a prescient forecast of [market dynamics](#) are not used widely.

To better understand these dynamics, we've modeled a theoretical "[microgrid](#)" in a residential subdivision, [Totarabank](#), in the North Island of Aotearoa.

We used the model to forecast the expected commercial returns from investing in microgrids and to unlock potential revenue streams from energy arbitrage.

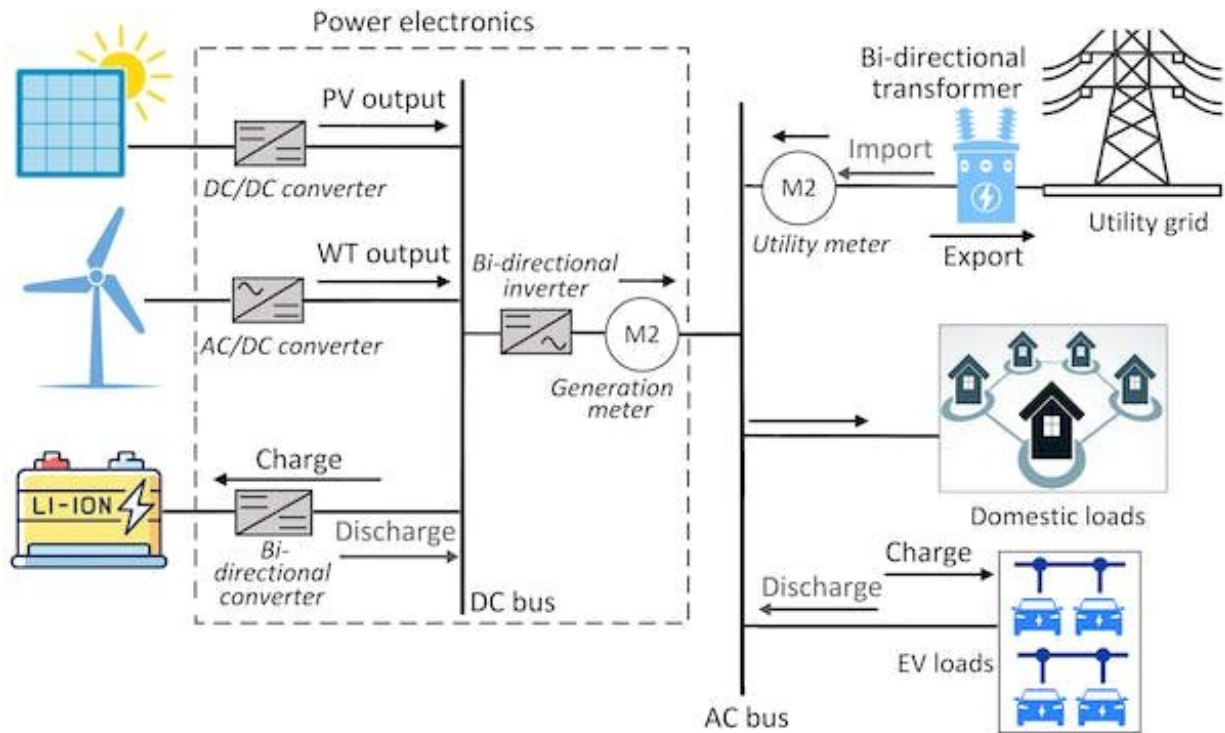

Smart scheduling of batteries

Energy arbitrage requires [battery storage](#) and [intelligent control](#) to make the most of a local renewable energy system's generation.

This can be achieved by forecasting short-term future electricity consumption and linking this to the spot power price on the market. [Sophisticated real-time controllers](#) then decide if the local system should store or sell to the market (or store and sell later).

Battery storage systems can vary in size, from [community-scale batteries](#) supplying a neighborhood to batteries within a fleet of electric vehicles

(EVs). The fundamental controlling processes required to achieve an optimal outcome are broadly the same, except that community batteries are stationary while EV batteries move around.

The modelled microgrid includes wind and solar power, a community battery and a fleet of electric vehicles. Author provided

Community batteries can store electricity purchased from the grid during off-peak periods and then discharge it during peak periods.

Neighborhoods with [solar power](#) can charge community batteries in the middle of the day when solar-generated electricity is abundant and discharge during the higher-priced evening peak.

EV batteries can be used similarly, using cheaper night rates or periods

of surplus wind during the night to charge. The energy stored in EV batteries can then be discharged into local loads or sold back into the grid when the price is highest, creating an additional revenue stream.

Modeling return on investment

In our modeling, we assumed the primary reasons people will invest in clean-energy technologies are sustainability, [energy independence](#) and resilience. We believe energy arbitrage could be an enabler of capital-intensive microgrids, as opposed to an investment made on a purely commercial basis.

Specifically, we considered a grid-connected microgrid integrating solar photovoltaic (PV) and wind turbines. The system is also backed by a community battery and has a fleet of ten personal EVs to serve.

We considered two scenarios: one with grid arbitrage revenues and one without.

Our results suggest revenues procured explicitly from energy arbitrage could reduce the total cost of the system by at least 12%. To put this into perspective, for a typical NZ\$10 million town-wide microgrid investment, this means \$1.2 million in savings.

Another interesting finding was that the length of time the batteries were able to sustain critical loads during [unplanned grid outages](#) was greater by about 16 hours per year, compared to the case without intelligent control. This is a remarkable resilience advantage.

So what does this kind of analysis mean for you? If you are part of a community interested in owning and operating a microgrid, you now have enough evidence to ask your developer to consider energy arbitrage so the community can participate in the electricity market to make a

profit.

If you own an EV and are trying to get cheaper night rates, this is a heads-up on future offerings from [electricity](#) retailers to get your storage-on-wheels to work with the vehicle-to-grid technology.

On the whole, energy arbitrage is an excellent tool to provide support for renewable energy investment decisions and help firm up revenue forecasts.
