Institute of Machinery and Materials (KIMM)

Korea Institute of Machinery & Materials (KIMM) has announced the development of the design and process technology for the world's first battery electrode that significantly improves the performance and stability of batteries used in electronic devices such as smartphones, laptops, and electric vehicles.

A joint research team led by principal researcher Seungmin Hyun of the Department of Nano-Mechanics at KIMM, an institution under the jurisdiction of the Ministry of Science and ICT, and Professor Hoo-jeong Lee of Sungkyunkwan University have developed a new battery technology that uses an electrode (anode) structure that enhances the reliability and performance of traditional lithium-ion batteries.

The results of their research achievement were published in the journal *Advanced Functional Materials*.

In order to develop a design and [process technology](#) that maintains [high performance](#) and reliability even when the electrode of the lithium-ion battery is thick, the KIMM-SKKU joint research team formed a bi-layered anode. Additionally, the anode is designed with grooves allowing small materials with improved ion conductivity and [electrical conductivity](#) to be placed between high-capacity materials.

In general, lithium-ion battery electrodes are manufactured by coating and drying a slurry so that it can be evenly distributed over the entire electrode. As such, it is the uniformity of the slurry that determines the performance of battery. The thicker the electrode, the lower the [energy density](#) and uniformity, making it difficult to maintain performance in a high-power environment.

However, with the anode structure of this newly developed battery, uniform reaction stability can be achieved while maintaining high energy density throughout the electrode, even if the electrode is thick. This is particularly helpful in improving the performance and lifespan of batteries.

Principal researcher Seungmin Hyun stated that this achievement is an

efficient method to improve the performance and lifespan of batteries by applying a new design to traditional lithium-ion battery materials and processes. He added that the team will continue to make efforts to apply this new technology to [electric vehicles](#) and soft robots that require high energy density in high-power environments, as well as to [electronic devices](#) such as commercial smartphones and laptops.
