

AI could make more work for us, instead of simplifying our lives, says researcher

There's a common perception that artificial intelligence (AI) will help streamline our work. There are even fears that it could wipe out the need for some jobs altogether.

But in a study of science laboratories I carried out with three colleagues at the University of Manchester, the introduction of automated processes that aim to simplify work—and free people's time—can also make that work more complex, generating new tasks that many workers might

perceive as mundane.

In the study, published in *Research Policy*, we looked at the work of scientists in a field called <u>synthetic biology</u>, or synbio for short. Synbio is concerned with redesigning organisms to have new abilities. It is involved in growing meat in the lab, in new ways of producing fertilizers and in the discovery of new drugs.

Synbio experiments rely on advanced, robotic platforms to repetitively move a large number of samples. They also use machine learning to analyze the results of large-scale experiments.

These, in turn, generate large amounts of digital data. This process is known as "digitalization," where <u>digital technologies</u> are used to transform traditional methods and ways of working.

Some of the key objectives of automating and digitalizing scientific processes are to scale up the science that can be done while saving researchers time to focus on what they would consider more "valuable" work.

Paradoxical result

However, in our study, scientists were not released from repetitive, manual or boring tasks as one might expect. Instead, the use of robotic platforms amplified and diversified the kinds of tasks researchers had to perform. There are several reasons for this.

Among them is the fact that the number of hypotheses (the scientific term for a testable explanation for some observed phenomenon) and experiments that needed to be performed increased. With automated methods, the possibilities are amplified.

Scientists said it allowed them to evaluate a greater number of hypotheses, along with the number of ways that scientists could make subtle changes to the experimental set-up. This had the effect of boosting the volume of data that needed checking, standardizing and sharing.

Also, robots needed to be "trained" in performing experiments previously carried out manually. Humans, too, needed to develop new skills for preparing, repairing, and supervising robots. This was done to ensure there were no errors in the scientific process.

Scientific work is often judged on output such as peer-reviewed publications and grants. However, the time taken to clean, troubleshoot and supervise automated systems competes with the tasks traditionally rewarded in science. These less valued tasks may also be largely invisible—particularly because managers are the ones who would be unaware of mundane work due to not spending as much time in the lab.

The synbio scientists carrying out these responsibilities were not better paid or more autonomous than their managers. They also assessed their own workload as being higher than those above them in the job hierarchy.

Wider lessons

It's possible these lessons might apply to other areas of work too. ChatGPT is an <u>AI-powered chatbot</u> that "learns" from information available on the web. When prompted by questions from online users, the chatbot offers answers that appear well-crafted and convincing.

According to Time magazine, in order for ChatGPT to avoid returning answers that were racist, sexist or offensive in other ways, <u>workers in</u> <u>Kenya</u> were hired to filter toxic content delivered by the bot.

There are many often invisible work practices needed for <u>the</u> <u>development and maintenance of digital infrastructure</u>. This phenomenon could be described as a "digitalization paradox." It challenges the assumption that everyone involved or affected by digitalization becomes more productive or has more free time when parts of their workflow are automated.

Concerns over a decline in productivity are a key motivation behind organizational and political efforts to automate and digitalise everyday work. But we should not take promises of gains in productivity at face value.

Instead, we should challenge the ways we measure productivity by considering the invisible types of tasks humans can accomplish, beyond the more visible work that is usually rewarded.

We also need to consider how to design and manage these processes so that technology can more positively add to human capabilities.
