

Using pulp and paper waste to scrub carbon from emissions

February 1 2024, by Victoria Martinez

Researchers at McGill University have come up with an innovative approach to improve the energy efficiency of carbon conversion, using waste material from pulp and paper production. The technique they've pioneered using the Canadian Light Source at the University of Saskatchewan not only reduces the energy required to convert carbon into useful products, but also reduces overall waste in the environment.

"This is a new field," says Roger Lin, a graduate student in chemical engineering "We are one of the first groups to combine biomass recycling or utilization with CO_2 capture." The research team, from McGill's Electrocatalysis Lab, has published <u>their findings</u> in the journal *RSC Sustainability*.

Capturing <u>carbon emissions</u> is one of the most exciting emerging tools to fight climate change. The biggest challenge is figuring out what to do with the carbon once the emissions have been removed, especially since capturing CO_2 can be expensive. The next hurdle is that transforming CO_2 into useful products takes energy. Researchers want to make the conversion process as efficient and profitable as possible.

"For these reactions, it really matters that we target <u>energy efficiency</u>," says Amirhossein Farzi, a Ph.D. student in chemical engineering at McGill. "The highest burden on the profitability of these reactions and these processes is usually how energy efficient they are."

Farzi, Lin, and their research team focused their efforts on changing out one of the most energy-intensive parts of the carbon <u>conversion process</u>.

Because the approach is so new, there are many questions to answer about how to get the purest outputs and best efficiency. The team used CLS beamlines to observe <u>chemical reactions</u> in real-time, mimicking industrial processes as closely as possible.

The researchers hope to expand the range of products that can be made with CO_2 , and help develop a truly green technology.

"If we use a renewable energy source like hydro, wind, or solar ...then in the end, we have really a carbon-negative process," says Lin.
