Created by nature, the human skin shows powerful sensing capabilities that have been pursued by scientists for a very long time. However, it is

challenging for today's technologies to replicate the spatial arrangement of the complex 3D microstructure of human skin.

A research team led by Professor Yihui Zhang from Tsinghua University has developed a three-dimensionally architected [electronic skin](#) that mimics human mechanosensation for fully-decoupled sensing of normal [force](#), shear force and strain.

[Their findings](#) were published in *Science*.

Taught by nature

Inspired by human skin, they created a three-dimensionally architected electronic skin with force and strain sensing components arranged in a 3D layout that mimics that of Merkel cells and Ruffini endings in human skin.

This 3DAE-Skin shows excellent decoupled sensing performances of normal force, shear force, and strain. It is the first-of-its-kind with force and strain sensing components arranged in a 3D layout that mimics that of slowly adapting mechanoreceptors in [human skin](#).

Enchanted by artificial intelligence

With the assistance of [artificial intelligence](#), they developed a tactile system for simultaneous modulus/curvature measurements of an object through touch. Demonstrations include rapid modulus measurements of fruits, bread, and cake with various shapes and degrees of freshness.

Credit: Tsinghua University

The resulting technology provides rapid measurement capabilities of the friction coefficient and the modulus of an object with diverse shapes, with potential applications in freshness assessment, biomedical diagnosis, [humanoid robots](#), prosthetic systems, among others.

Zhang's study was done with colleagues from Tsinghua University's Applied Mechanics Laboratory, Department of Engineering Mechanics and Laboratory of Flexible Electronics Technology.
