A joint research team from the School of Energy and Chemical Engineering and the Department of Chemistry at UNIST has addressed critical challenges in perovskite solar cell (PSC) production, significantly enhancing both their efficiency and stability, which is expected to further bolster their commercialization potential.

Led by Professors Jin Young Kim, Dong Suk Kim, and Geunsik Lee, the team successfully achieved [precise control](#) over ion arrangement and reduced structural irregularities by incorporating a bidirectional coordinator between the [perovskite](#) photoactive layer and the electron transport layer.

The work is [published](#) in the journal *Energy & Environmental Science*.

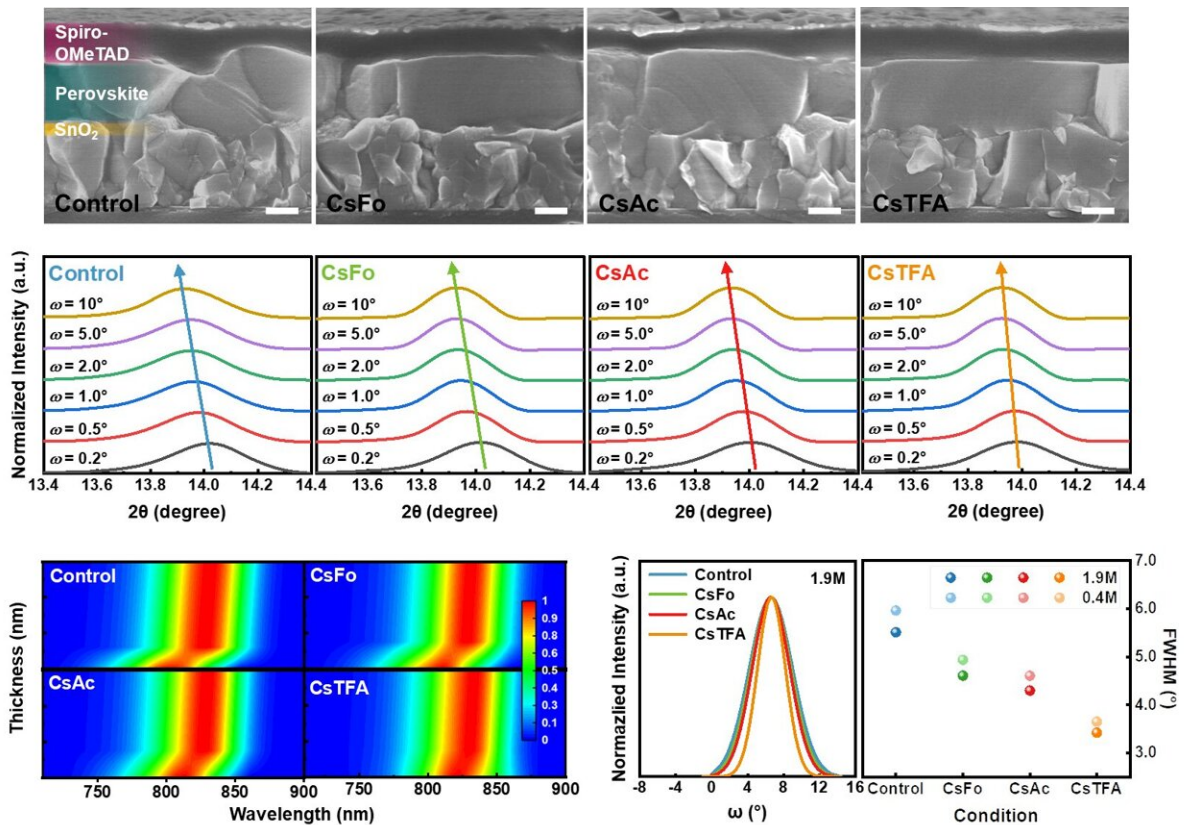

Despite their high efficiency and low manufacturing costs, perovskite [solar cells](#) have faced obstacles to commercialization due to various defect-related issues. The research team introduced trifluoroacetate (TFA⁻) ions between the perovskite layer and the tin oxide substrate, which serves as the electron transport layer (ETL), to mitigate these defects.

The carboxylate group (-COO⁻) of TFA⁻ firmly bonds with the tin oxide, enhancing [structural stability](#). Simultaneously, the organic head group (-CF₃) effectively reduces defects through bidirectional molecular tuning that interacts with the perovskite layer.

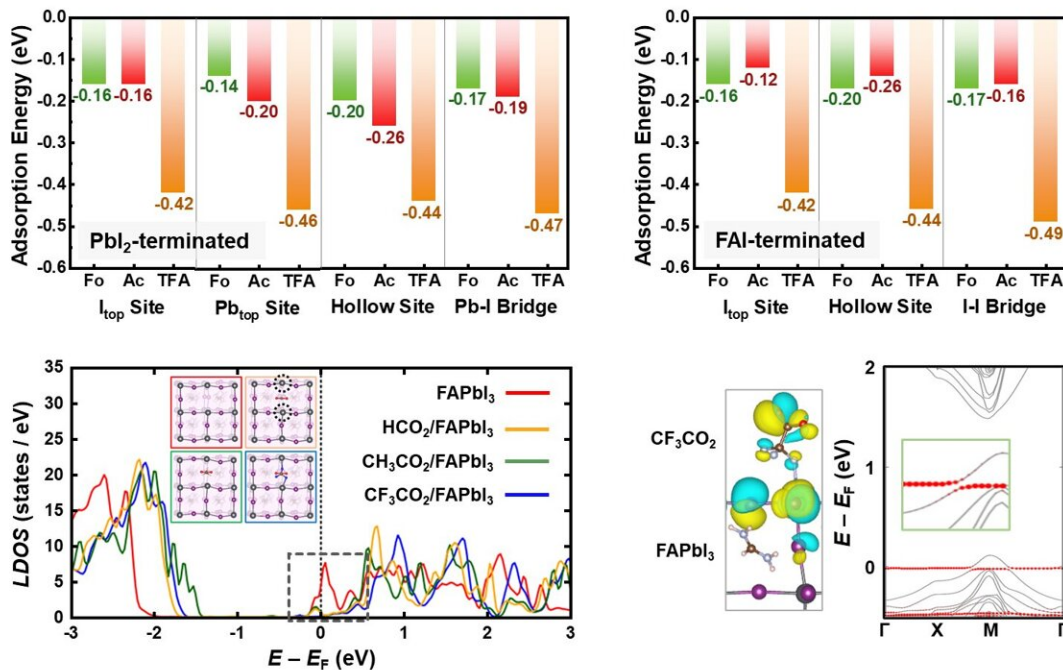

This approach allowed the research team to control the irregular structure of the perovskite thin film, substantially improving charge carrier mobility.

The resulting perovskite films, characterized by the absence of buried

interfaces and minimized tensile strain, achieved a remarkable power conversion efficiency (PCE) of 25.60%. Moreover, the unencapsulated device maintained over 80% of its initial PCE even under prolonged light exposure after 1,000 hours.

(a) Cross-sectional SEM images of the perovskite films deposited on the control- and CsX-treated SnO₂, configured as FTO/control- and CsX-treated SnO₂/Perovskite/Spiro-OMeTAD. (b) GIXRD spectra of the perovskite films deposited on the control- and CsX-treated SnO₂ upon varying the grazing incidence angle from 0.2° to 10°. (c) Normalized PL spectra upon varying the thickness of the perovskite films deposited on the control- and CsX-treated SnO₂. (d) XRD rocking curves of the perovskite films deposited on the control- and CsX-treated SnO₂ (left). FWHM values of XRD rocking curves of perovskite films with different concentrations, 0.4 M and 1.9 M, deposited on the control- and CsX-treated SnO₂ (right).

Professor Dong Suk Kim remarked, "This groundbreaking bidirectional coordination strategy reveals a promising pathway to enhance high efficiency and confront the persistent challenge of addressing long-term stability concerns. This achievement will further enhance the commercialization potential of PSCs."
